
How To Sleep With Your Eyes Open

UNDERSTANDING NOCTURNAL LAGOPHTHALMOS: *Published by Psychology Today*
How To Sleep With Your Eyes Open by *Adkins & Fernanda*

INTRODUCTION: THE CURIOUS CASE OF SLEEPING WITH EYES OPEN

Have you ever been told that you or someone you know “sleeps with their eyes open”? It sounds like a superhuman trick or a scene from a horror movie, but in reality, it is a known condition called nocturnal lagophthalmos. Contrary to the literal interpretation of the phrase, sleeping with your eyes open does not mean you are fully awake and aware; rather, it describes a partial or complete inability to close the eyelids during sleep. This phenomenon is more common than you might think, affecting an estimated 5% to 25% of the population at some point in their lives. Whether you are simply curious or are looking for practical advice on how to sleep with your eyes open—perhaps because of a medical condition, lifestyle necessity, or a unique work requirement—this article will explore the science, risks, and techniques involved. We will separate fact from fiction, provide actionable tips, and explain why you should approach this topic with caution. Let’s dive deep into the mechanics of open-eye sleep and what it really means for your health and daily life.

WHAT IT ACTUALLY MEANS

The medical term for sleeping with your eyes open is nocturnal lagophthalmos. It occurs when the orbicularis oculi muscle—the muscle responsible for closing the eyelids—fails to contract fully during sleep. This can happen for several reasons, including facial nerve palsy (such as Bell’s palsy), stroke, trauma, thyroid eye disease, or even as a side effect of certain medications. In some cases, it is simply an anatomical variation where the eyelids do not fully cover the eyes. Many people who sleep with their eyes open are unaware of it, often first learning from a partner or family member who notices gaps in their eyelids during the night.

It is crucial to understand that “how to sleep with your eyes open” is not a skill you can learn through practice—it is usually an involuntary condition. Attempting to force your eyes open while asleep is not safe and can lead to serious eye damage. However, for those who already experience mild lagophthalmos, lifestyle adjustments can help protect the eyes and improve sleep quality. In this article, we will discuss safe and practical strategies for managing this condition, as well as when to seek professional medical help.

EYES OPEN?

Before we delve into the “how,” let’s address the “why.” Most people want to know about this topic for one of three reasons:

1. **Medical curiosity** – You or a loved one may have been diagnosed with lagophthalmos and are looking for management strategies.
2. **Performance or safety** – Some professions (e.g., military personnel, night shift workers, or extreme athletes) might believe that sleeping with eyes open allows them to remain partially alert. However, this is a myth—true restorative sleep requires closed eyes.
3. **Misinformation** – Some online “life hacks” suggest that sleeping with eyes open can save time or increase awareness. These claims are unfounded and dangerous.

We will focus on the first category: how to safely manage involuntary open-eye sleep. If you are attempting to learn this as a “trick,” we strongly advise against it, as it can lead to dry eyes, corneal ulcers, infections, and permanent vision damage.

CAN YOU REALLY SLEEP WITH YOUR EYES OPEN? THE SCIENCE BEHIND THE MYTH

The short answer is yes, some people can and do sleep with their eyes partially or fully open, but it is not a normal or healthy state. The brain’s sleep control centers actively signal the eyelids to close as part of the natural sleep onset process. When this signal

is disrupted, the eyes are exposed to air and light. During rapid eye movement (REM) sleep, your eyes move behind closed lids; if the lids are open, the eyes are still moving, but they are vulnerable to drying and mechanical irritation.

Research shows that even a small gap in eyelid closure can cause significant tear film evaporation. The cornea, which is the clear front surface of the eye, relies on a constant layer of tears for oxygen and lubrication. Without adequate protection, the cornea can become desiccated, leading to blurred vision, redness, pain, and increased risk of infection. So, while sleeping with eyes open is possible for some, it is rarely without consequences.

RISKS AND SIDE EFFECTS OF SLEEPING WITH EYES OPEN

If you or someone you know sleeps with their eyes open, it is essential to understand the potential health risks:

- **Dry eye syndrome** – The most common complication, leading to a gritty, burning sensation upon waking.
- **Corneal abrasion** – Friction from the eyelid or pillow against a dry cornea can cause scratches.
- **Infections** – Bacteria or dust can enter the eye more easily without the protective blink reflex.
- **Photophobia** – Light entering through partially open lids can disrupt sleep and increase sensitivity.
- **Vision problems** – Chronic exposure to air can lead to corneal scarring and blurred vision.
- **Chronic inflammation** – Long-term lagophthalmos may cause conjunctivitis or blepharitis.

Therefore, the goal of any “how to sleep with your eyes open” strategy is not to encourage the behavior, but to minimize harm and protect your eyesight.

HOW TO SLEEP WITH YOUR EYES OPEN SAFELY: PRACTICAL MANAGEMENT STRATEGIES

If you have been diagnosed with nocturnal lagophthalmos or suspect you sleep with your eyes open, the following steps can help you manage the condition safely. Always consult an ophthalmologist before trying any new treatment.

1. Use a Humidifier in Your Bedroom

Dry air exacerbates eye moisture loss. Running a cool-mist humidifier in your bedroom can increase ambient humidity, slowing tear evaporation and keeping your eyes more comfortable during the night.

2. Apply Overnight Protective Ointments

Over-the-counter lubricating ointments or gels (such as artificial tears in gel form) can be applied just before sleep. Unlike daytime drops, these are thicker and create a protective film over the eye. They may cause temporary blurriness upon waking, but they

provide crucial moisture throughout the night.

3. Wear Eye Masks or Goggles

A tightly-fitting sleep mask can physically hold the eyelids closed and block out light. Some people find that a simple soft cloth mask works well. For more severe cases, ophthalmologists may recommend moisture-chamber goggles, which seal around the eyes to trap humidity.

4. Tape the Eyelid Closed (Under Medical Supervision)

In extreme cases, a doctor may advise using hypoallergenic medical tape to gently keep the eyelids shut. This must be done carefully to avoid damaging the delicate skin around the eyes. Never use standard tape; ask your doctor for a specific product and demonstration.

5. Optimize Your Sleep Position

Sleeping on your back may cause the eyelids to fall open more easily due to gravity. Sleeping on your side or stomach can sometimes help keep the lids shut. You can also place a soft pillow against your face to provide gentle pressure that encourages eyelid closure.

6. Use Eye Drops Before Bed and Upon Waking

Preservative-free artificial tears can be used just before sleep and immediately after waking to rehydrate the eyes. Avoid overusing drops with preservatives if you will be using them multiple times during the night (though these are generally safe for single doses).

7. Address Underlying Causes

If your open-eye sleep is due to a medical condition—such as thyroid eye disease, Bell’s palsy, or a neurological issue—treating the root cause is essential. Work with your primary care doctor or

a specialist to manage the underlying problem. For example, thyroid eye disease may require anti-inflammatory medications or even surgery.

8. Consider Eyelid Weights or Surgical Options

In severe cases, an ophthalmologist might recommend surgically implanting a small gold or platinum weight into the upper eyelid. This weight uses gravity to help close the eye during sleep. Alternatively, tarsorrhaphy (a procedure that narrows the eye opening) may be performed. These are last-resort treatments but can be highly effective.

COMMON MYTHS ABOUT SLEEPING WITH EYES OPEN

Let’s clear up some misconceptions:

- **Myth:** Sleeping with eyes open means you are still alert. **Fact:** The brain does not process visual information during sleep, even if the eyes are partially open. You will not be able to see or react to your surroundings.
- **Myth:** It is a sign of deep sleep. **Fact:** It is often associated with lighter sleep stages and can lead to sleep fragmentation.
- **Myth:** You can train yourself to do it. **Fact:** Eyelid closure is an involuntary reflex that cannot be overridden permanently without risk of injury.
- **Myth:** Sleeping with eyes open is always dangerous. **Fact:**

Many people have mild lagophthalmos without serious problems, especially if they produce enough tears or sleep in a humid environment.

WHEN TO SEE A DOCTOR

If you experience any of the following symptoms, schedule an appointment with an eye doctor or sleep specialist:

1. Persistent dry eyes upon waking, especially with pain or redness.
2. Blurred vision that improves after blinking or using drops.
3. Frequent eye infections or corneal ulcers.
4. A history of facial paralysis (Bell's palsy, stroke) or trauma around the eyes.
5. Poor sleep quality or excessive daytime sleepiness (which could be related to disruptive light entering the eyes).

A simple test called “slit lamp examination” can determine if your eyelids close completely. Your doctor may also measure your tear film stability or refer you to a sleep clinic if other sleep disorders are suspected.

ALTERNATIVE APPROACHES: LIFESTYLE ADJUSTMENTS FOR BETTER EYE HEALTH

Beyond direct interventions, consider these holistic habits to support eye moisture:

- **Stay hydrated** – Drink enough water throughout the day to maintain tear production.
- **Eat omega-3 fatty acids** – Found in fish, flaxseed, and walnuts, they can improve oil gland function in the eyelids.
- **Avoid smoke and drafts** – Smoke, ceiling fans, and air conditioning can dry out eyes faster.
- **Practice good eyelid hygiene** – Gently clean the eyelid margins with a warm compress to keep glands healthy.

CONCLUSION: PROTECT YOUR EYES, PRIORITIZE REAL SLEEP

Sleeping with your eyes open is not a cool ability to be mastered—it is a medical condition that requires awareness and care. The phrase “how to sleep with your eyes open” should be approached with caution, focusing on harm reduction rather than achievement. By implementing the practical strategies outlined above—using humidifiers, lubricating ointments, sleep masks, and consulting a specialist—you can protect your eyes and improve your sleep quality. Remember, true, restorative sleep happens when your eyelids are fully closed, your brain is off-duty, and your eyes are safely bathed in tears. If you suspect you or a loved one has nocturnal lagophthalmos, take action today. Your vision and your sleep are too precious to risk.

Have you ever woken up with gritty, dry eyes? Share your experience with a healthcare professional and explore the simple changes that can make a world of difference.
